TITLE OF INVENTION

UNIVERSAL MODULATOR

APPLICANT(S) FOR DO/EO/US

Matthew G. Waight and Dipakkumar R. Patel

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:

1. ☒ This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371.
2. ☐ This is a **SECOND** or **SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371.
3. ☐ This is an express request to begin national examination procedures (35 U.S.C. 371(f)). The submission must include items (5), (6), (9) and (21) indicated below.
4. ☐ The US has been elected by the expiration of 19 months from the priority date (Article 31).
5. ☒ A copy of the International Application as filed (35 U.S.C. 371(c)(2))
  - a. ☒ is attached hereto (required only if not communicated by the International Bureau).
  - b. ☐ has been communicated by the International Bureau.
  - c. ☐ is not required, as the application was filed in the United States Receiving Office (RO/US).
6. ☐ An English language translation of the International Application as filed (35 U.S.C. 371(c)(2)).
  - a. ☐ is attached hereto.
  - b. ☐ has been previously submitted under 35 U.S.C. 154(d)(4).
7. ☒ Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3))
  - a. ☐ are attached hereto (required only if not communicated by the International Bureau).
  - b. ☐ have been communicated by the International Bureau.
  - c. ☐ have not been made; however, the time limit for making such amendments has NOT expired.
  - d. ☒ have not been made and will not be made.
8. ☐ An English language translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371 (c)(3)).
9. ☒ An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4)).
10. ☐ An English language translation of the annexes of the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)).

## Items 11 to 20 below concern document(s) or information included:

11. ☐ An Information Disclosure Statement under 37 CFR 1.97 and 1.98.
12. ☐ An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.
13. ☐ A FIRST preliminary amendment.
14. ☐ A SECOND or SUBSEQUENT preliminary amendment.
15. ☐ A substitute specification.
16. ☐ A change of power of attorney and/or address letter.
17. ☐ A computer-readable form of the sequence listing in accordance with PCT Rule 13ter.2 and 35 U.S.C. 1.821 - 1.825.
18. ☐ A second copy of the published international application under 35 U.S.C. 154(d)(4).
19. ☐ A second copy of the English language translation of the international application under 35 U.S.C. 154(d)(4).
20. ☒ Other items or information:  
Eight (8) sheets of drawings, in triplicate; copy of the International Publication with Search Report; copy of the International Preliminary Examination Report; copy of the Written Opinion; copy of the Reply to Written Opinion; and Application Data Sheet

UNIVERSAL MODULATOR

**BACKGROUND**

The present invention generally relates to cable television (CATV) and consumer video communication systems.

5 More particularly, the invention relates to a dual-conversion universal modulator having programmable synthesized phase-locked loop oscillators driving their respective mixers which select a specific HI-IF frequency depending upon what output frequencies or standards are desired. Such standards include  
10 NTSC, PAL, NICAM, DIN, SECAM and any other known standard.

To allow reception of more than the 12 VHF channels on an older television receiver, most CATV systems require a settop terminal at a subscriber's location. Today, settop terminals not only provide a means for accepting a plurality  
15 of channels broadcast with varying bandwidths and guardbands for forward and reverse frequencies, but they also secure pay television services from unauthorized viewing. Other functions include decoding digital video and audio, interactive services, creating personalized viewer channels  
20 and the like.

In addition to the conversion from a cable transmission to a standard output frequency, a variety of descrambling techniques are employed depending upon the techniques used at a system headend. CATV equipment manufacturers are  
25 developing more sophisticated scrambling techniques using complicated encryption methods and digital processing to thwart pirating.

Most settop terminals are tunable. A block diagram for a prior art settop terminal is shown in **Figure 1**. Incoming signals from a CATV transmission network are coupled to an input bandpass amplifier and up-converted to a high intermediate frequency (HI-IF). The up-conversion requires a tunable local oscillator which selects a desired channel and an associated mixer. The mixer is coupled to a bandpass filter and down-converted to an IF channel using a fixed-frequency local oscillator and mixer. The output channel is filtered and forwarded to a subscriber's television receiver. Prior art settop terminals use one down-converter mixer with an oscillator having slight frequency agility to provide an output at one or two preselected channel frequencies. The output frequencies and bandwidths depend upon the transmission standard used.

In the United States, the NTSC (National Television System Committee) is the standard for color television. Other countries have chosen different systems. SECAM (*sequentiel couleur avec mémoire*) is used by France and Russia. PAL A and PAL B (phase alternation line) are used by many European countries such as Germany and the United Kingdom. Accordingly, television receivers are typically manufactured for a specific transmission standard. For worldwide use, a settop terminal must be adapted to the established broadcast standards.

U.S. Patent No. 5,640,697 teaches the use of two predetermined frequencies for each local oscillator, whereby the second oscillator frequency can be adjusted independently of the first oscillator frequency. Adjustment between the two

frequencies is used to adapt to the different output frequencies, while eliminating noise caused by the local oscillators. Similar to U.S. Patent No. 5,640,497, German Patent No. Application 4,306,578 adjusts the oscillator frequencies by a predetermined amount in order to eliminate noise. PCT International Patent Application No. 84/04637 employs two local oscillators that generate predetermined frequencies, in which the second oscillator is selected between one of two frequencies to eliminate this noise.

Accordingly, there exists a need for an inexpensive method to adapt the output of a settop terminal to a variety of television broadcast standards.

## SUMMARY

The present invention is a universal modulator that accepts baseband audio and video inputs and modulated audio or data and converts the combined signal to one of a plurality of frequencies in dependence upon a desired output frequency and broadcast standard. The universal modulator is located between baseband video and audio outputs of a settop terminal demodulator/decoder and an antenna input of a television receiver or other audio/video component (such as a VCR). The universal modulator includes a dual conversion architecture using an up-converter mixer and a down-converter mixer. Each mixer receives an oscillator input from a corresponding addressable, programmable, PLL (phase-locked loop) frequency synthesizer. Each PLL frequency is controlled by firmware in the settop terminal. Configuration is performed via manual input using settop terminal controls, or interrogation directly by the CATV headend or by programmed settings. A communication bus coupled to the firmware distributes addressable instructions to selectively control each PLL frequency and obviate oscillator difference beat frequencies (ODBFs) that may be manifested.

Accordingly, it is an object of the present invention to provide a universal modulator within a settop terminal which is able to couple a CATV transmission network to a customer's television receiver notwithstanding the broadcast standard used to transmit the television programs.

Other objects and advantages will become apparent to those skilled in this art after reading the detailed description of the preferred embodiment.

#### BRIEF DESCRIPTION OF THE DRAWINGS

5           **Figure 1** is a block diagram of a prior art CATV settop terminal.

**Figure 2** is a block diagram of a settop terminal incorporating the present invention.

10           **Figure 3** is a block diagram of the preferred embodiment of the universal modulator of the present invention for use in a settop terminal.

**Figure 4** is a block diagram of an addressable, programmable, phase-locked loop.

15           **Figure 5** is a flow chart of the universal modulator configuring process.

**Figure 6** is a flow chart of the ODBF translation process.

**Figure 7** is a block diagram of a prior art headend.

20           **Figure 8** is a block diagram of a headend made in accordance with the present invention.

**Figures 9A and 9B** are graphs of oscillator difference beat frequencies.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

25           The preferred embodiment will be described with reference to the drawing figures where like numerals represent like elements throughout.

**Figure 2** is a block diagram of a settop terminal **17** with the universal modulator **19** shown coupled to the output of a demodulator/decoder **21**. The demodulator/decoder **21** outputs a customer's channel selection as baseband audio **23** and video **25**. The functional description of the demodulator/decoder **21** is beyond the scope of the present invention **19** and shall not be described. An alternate audio source **27**, such as a NICAM carrier or modulated audio, may also be supplied and output **29**.

The higher quality baseband audio **23** and video **25** signals are available as settop terminal outputs **31**, **33** and may be coupled to television receivers that have baseband inputs. For television receivers that lack this feature, the universal modulator **19** provides an up-conversion output **35** compatible with the television broadcast standard used, from baseband to VHF or UHF for coupling to an antenna input.

The demodulator/decoder **17** outputs baseband audio **23** and video **25** and an alternate audio carrier **27** which differs from the baseband audio output. A reference clock signal **37** originating from a master oscillator and a common communication bus **39** are also coupled to the modulator **19**.

The universal modulator **19** is shown in more detail in **Figure 3**. The common communication bus **39** shown is an I<sup>2</sup>C interface from Phillips® Electronics. Other bus communication protocols may alternatively be used. The configuration for a settop terminal **17** may be downloaded from the CATV system headend via a dedicated channel, or inband on the VBI of a channel. One skilled in this art would

appreciate that an advanced cable system can address and interrogate a specific settop terminal and alter its functionality. If the settop terminal has all configurations stored in firmware, the CATV system headend may simply instruct the settop terminal 17 of the standard being used. In this fashion, the settop terminal 17 does not require a technician to configure the unit but can auto-configure upon initial energization.

The communication bus protocol permits configuring component parameters to a particular broadcast standard using a unique addressing system within the settop terminal 17. As shown in **Figure 3**, the I<sup>2</sup>C bus 39 communicates with: a baseband audio programmable PLL frequency synthesizer 41, a second audio carrier switched input 43, adjustable amplifiers for the baseband video input 45 and baseband audio input 47, a programmable PLL frequency synthesizer 49 for an up-converter mixer 91 and a programmable PLL frequency synthesizer 51 for a down-converter mixer 101. Although third addressable programmable PLL 51 has been described as being coupled to a "down-converter" mixer 101, the down-converter mixer 101 may in fact further up-convert the HI-IF signal to a higher frequency signal. It should be noted that each PLL frequency synthesizer 41, 49, 51 has an associated oscillator driver L01, L02, L03 respectively (not shown). Each respective component has its own address to permit firmware contained parameters to be loaded for a given broadcast standard configuration.

The alternate audio input 53, modulated by the demodulator/decoder 21, is coupled to the solid state switch 43. The output of the switch 43 is coupled to a first input 55 of a summing amplifier 57. The baseband video input 59 is coupled to a clamp 61 which limits signal amplitude. The output from the clamp 61 is coupled to the video adjustable amplifier 45 where signal gain is increased or attenuated depending upon the broadcast standard. The output from the adjustable amplifier 45 is coupled to a hard limiter 63 which clips signal peaks. The output from the limiter 63 is coupled to a second input 65 of the summing amplifier 57. The baseband audio input 67 is coupled to a baseband audio mixer 69 via an adjustable amplifier 68. The baseband audio mixer 69 modulates the baseband to the broadcast standard. The baseband audio mixer 69 may be selectively activated or deactivated by the I<sup>2</sup>C bus as required to support the standard in use. The output from the baseband audio mixer 69 is coupled to a lowpass filter 71 to remove RF. A second input to the audio lowpass filter 71 is provided as a modulated audio input 72. The audio lowpass filter 71 is coupled to an audio adjustable amplifier 47 where signal gain is increased or attenuated. The audio adjustable amplifier 47 output is coupled to a third input 73 of the summing amplifier 57.

Each of the mixers mix a signal input with the outputs of the three addressable, programmable PLL frequency synthesizers 41, 49, 51. The PLL output frequencies vary depending on the broadcast standard and the RF output

frequency 105 desired. An addressable, programmable PLL frequency synthesizer 41, 49, 51 is shown in Figure 4.

5 The PLL 41, 49, 51 includes a phase detector 75, a voltage-controlled oscillator (VCO) 77 and a loop filter 79. The programmable PLL uses digital and analog techniques for frequency synthesis. The phase detector 75 compares two input frequencies 81a, 81b and generates an output 83 that is a measure of their phase difference. If both inputs 81a, 81b differ in frequency, the output is periodic at the difference frequency. If the frequency input does not equal the frequency output of the VCO 77, the phase-error signal, after being filtered, causes the VCO frequency to deviate in the direction of the input frequency. When the frequencies match, the VCO 77 locks to the input frequency maintaining a fixed phase relationship with the input signal. The filtered output of the phase detector 75 is a dc signal. A modulo- $n$  counter 87 is coupled between the VCO 77 output and the second input 81a to the phase detector 75 to generate a multiple of the input reference frequency providing frequency synthesis.

20 Each PLL synthesizer 41, 49, 51 employed in the present invention 19 is addressable such that the input frequency can be adjusted by using an input modulo- $n$  counter 89 or divide-by- $n$  to adjust output frequency. Both the input frequency divide-by- $n$  89 and loop frequency divide-by- $n$  87 are addressable components. Each of the PLLs 41, 49, 51 are addressed and controlled in accordance with a predetermined

settop terminal 17 configuration. The configuration determines both the output frequency and operating bandwidth of the settop terminal 17 and adjusts the up- and down-converter PLLs 49, 51 accordingly.

5 Referring back to **Figure 3**, the summer amplifier 57 output is modulated with the frequency output from the second programmable PLL 49 to drive the up-conversion modulator 91 and translate the summed output to a high intermediate frequency (HI-IF) 93. The HI-IF 93 is higher than the  
10 highest expected frequency in the summed amplifier 57 output bandwidth. In the present invention 19, the input to the up-converter mixer 91 is not bandwidth limited.

The summing amplifier 57 output frequencies are translated to a new bandwidth, starting at a low frequency of  
15 the second PLL 49 minus the highest input band frequency, and ending at a high frequency of the third PLL 51 minus the lowest input band frequency. The second PLL 49 frequency is selected to translate the summing amplifier 57 output to correspond to the passband of an intermediate lowpass filter  
20 95. The output from the lowpass filter 95 is coupled to a buffer amplifier 97 to restore gain losses. The output from the buffer amplifier 97 is input to a final lowpass filter 99. The buffer amplifier 97 maintains the system noise figure by overcoming the losses in the up-conversion mixer 91  
25 and first HI-IF filter 95. The signal is filtered by a HI-FI filter 99, with the output coupled to a down-conversion mixer 101. The third PLL synthesizer 51 is coupled to the down-conversion mixer 101. The difference between the HI-IF 93

and the third PLL 51 frequency is the desired output channel in the IF band. It should, however, be noted that the down-converter mixer 101 may accept the HI-IF 93 and further up-convert the signal to a higher frequency RF signal. The output is then filtered via a low pass filter 103, (or other appropriate filter if up-converted), and forwarded as an RF output frequency 105 for reception by a television receiver.

As discussed above, the second 49 and third 51 programmable PLLs are controlled by the common communication bus 39. The bus 39 is coupled to a processor in the settop terminal demodulator/decoder 21 which receives instructions from the system headend or from the settop terminal's 17 keypad. The configuration takes place transparently upon initial energization of the unit 17 if the system headend is equipped to send broadcast configuration instructions to the settop terminal 17. If the system headend does not have this capability, the settop terminal 17 is configured via the keypad and function display (not shown). The configuration request, whether from the headend or at a consumer location, outputs the predetermined parameters onto the I<sup>2</sup>C bus 39 for each of the addressable components. The predetermined parameters are related to the standard that is being employed by the CATV system on which the settop terminal 17 is located. These parameters will include the determination of whether a second audio carrier 53 exists, whether the baseband audio input 67 or the modulated audio input 72 are to be used and the frequency at which the RF output frequency 105 is desired. These parameters may also include any other

configurable parameters which are employed by any of the addressable components coupled to the communication bus 39. It should also be recognized that since many of the components are addressable by the communication bus 39, a user may manually input and address a particular component and selectively configure that component if desired.

An undesirable artifact of dual conversion is the generation of harmonics based on the fundamental oscillator frequencies. The harmonics of the second and third PLL frequency synthesizers 49, 51 mix with each other, thereby creating ODBFs. To obviate the intrusive effects of these PLL harmonics, the system and method of the present invention 19 eliminate this type of interference by translating the significant ODBFs out of the desired output channel.

A flowchart of the preferred method of the present invention 19 is shown in Figure 5. Upon making the necessary connections to the CATV cable 15 and subscriber's television receiver, the settop terminal 17 is energized (step 201) establishing communication with the system headend. If the cable system headend has forward communication ability (step 205), the settop terminal is instructed how to configure itself for the applicable broadcast standard by downloading the parameters for the regional standards being used and the channel broadcast maps (step 207). The predetermined PLL frequencies derived from the channel and broadcast maps in memory are converted into corresponding "divide-by" numbers for the PLL modulo-*n* converters 87, 89 and output to the second 49 and third 51 PLL frequency synthesizers. The

settop terminal **17** acknowledges when configuration is complete. If the cable system does not have forward communication capability, the user will be prompted to enter the applicable information via a display and keypad, thereby manually loading the applicable broadcast configuration (**step 209**).

The settop terminal **19** reviews the loaded channel and broadcast maps. The predetermined frequencies are examined for potential ODBFs (**step 211**). If it is determined that ODBF's are likely (**step 213**), an ODBF translation is performed (**step 215**) as shown in **Figure 6** (which will be explained in greater detail hereafter). Otherwise, the original frequencies are maintained (**step 217**) (**Figure 5**). The frequencies are addressed to their respective PLL synthesizers as words over the I<sup>2</sup>C communication bus (**step 219**).

Referring to the flow diagram of **Figure 6**, the elimination of ODBFs is achieved by selectively adjusting the frequencies of the second **49** and third PLLs **51** to obtain the desired RF output frequency. For a typical NTSC signal, the up-converter mixer **91** modulates the input video **59** and audio signals **67** with the output **93** of the second PLL **49** to up-convert the input RF signal of the selected channel to the HI-IF **93** (**step 301**).

$$LO1 = \text{audio carrier frequency} \quad (\text{Equation 1})$$

$$LO2 = HI - IF \quad (\text{Equation 2})$$

The down-converter mixer mixes **101** the HI-IF **93** with the output of the third PLL synthesizer **51 (step 303)** to down-convert, (or further up-convert if desired), to obtain the desired RF output frequency **105**.

$$LO3 = (HI - IF) + RF \text{ output} \quad (\text{Equation 3})$$

Multiples of the second and third PLL synthesizer **49, 51** fundamental frequencies define the even and odd harmonics,

$$m(LO2) \text{ and } m(LO3), \text{ for } m = 1, 2, 3, 4, \dots \infty, \quad (\text{Equation 4})$$

which represent all possible harmonics (**step 305**). However, due to the high system frequencies involved, examination of frequencies beyond the 10th harmonic is unnecessary.

The existence of an interfering ODBF is determined by serially calculating the differences between two harmonics of the second **49** and **51** third PLL synthesizers that are separated by at least one degree until the absolute value of an  $ODBF_{m,n}$  is within a given bandwidth or a predetermined number of  $ODBF_{m,n}$  values are calculated. When an  $ODBF_{m,n}$  absolute value is found within the RF channel bandwidth, it is designated as an interfering oscillator difference beat frequency (ODBF). The general equation for calculating ODBFs is:

$$ODBF_{m,n} = (m + n) (LO2) - (m)(LO3), \text{ for } m = 1, 2, 3, 4, \dots 10,$$

(Equation 5)

with  $n = 1$  for a first series,  $n = 2$  for a second series,  $n = 3$  for a third series, and so on up to  $n = 8$  for all previously calculated harmonics (step 305). The  $ODBF_{m,n}$  calculated from the differing degrees of the second 49 and third PLL 51 harmonics are then examined (step 307). For example, if the ODBF lies outside of the desired RF output channel bandwidth, no adjustment of the second 49 and third 51 PLL frequency synthesizers is required.

For an ODBF which falls inband, the following equations can be used to determine which direction the second 49 and third 51 PLL frequencies should be adjusted to translate the ODBF out of band. In these equations, CLB is the channel low-band; CMB is the channel mid-band; and CHB is the channel high-band.

If  $-CHB \leq ODBF < -CMB$ ; then HI-IF is moved downward. (Equation 6A)

(If the result of Equation 5 is negative and the magnitude is greater than the mid-band of the desired RF output channel (step 309), the HI-IF is moved downward (step 311)).

If  $-CMB \leq ODBF \leq -CLB$ ; then HI-IF is moved upward. (Equation 6B)

(If the result of Equation 5 is negative and the magnitude is less than or equal to the mid-band of the desired RF output channel (step 313), the HI-IF is moved upward (step 315)).

If  $CLB \leq ODBF \leq CMB$ ; then HI-IF is moved downward. (Equation 6C)

(If the result of Equation 5 is positive and the magnitude is less or equal to than the mid-band of the desired RF output channel (step 317), the HI-IF is moved downward (step 319)).

If  $CMB < ODBF \leq CHB$ ; then HI-IF is moved upward. (Equation 6D)

(If the result of Equation 5 is positive and the magnitude is greater than the mid-band of the desired RF output channel (step 321), the HI-IF is moved upward (step 323)).

The second 49 and third 51 PLLs are then adjusted (step 327) in accordance with the following: To translate the oscillator difference beats below or above the desired RF output channel, the following equation is used to determine the  $\Delta$  in

frequency for the second 49 and third 51 PLL frequency synthesizers.

$$\Delta = \frac{\text{CMB} - [(m+n)(\text{LO2}) - m(\text{LO3})]}{(m+n) - m} \quad (\text{Equation 7})$$

The new second 49 and third 51 PLL frequencies (LO2' and LO3' respectively) are derived as shown in LO2' is calculated as shown in Figure 6.

The new PLL frequencies LO2' and LO3' translate the ODBFs above or below the desired RF output channel. The new PLL frequency values are used to program the second 49 and third 51 PLL frequency synthesizers (step 327).

In an alternative embodiment, a fixed value for  $\Delta$  can be used to simplify the calculations and the operation of the system. For example, a value of 4 MHz for  $\Delta$  will suffice for NTSC and PAL systems.

The present invention will now be explained with reference to several examples. In the first example, if the HI-IF is 960 MHz and the desired RF output channel has a picture carrier frequency of 319.25 MHz, we have the following:

$$\text{LO2} = \text{HI-IF} = 960 \text{ MHz; and} \quad (\text{from Equation 2})$$

$$\begin{aligned} \text{LO3} &= \text{HI-IF} + \text{RF output} && (\text{from Equation 3}) \\ &= 960 + 319.25 = 1279.25 \text{ MHz.} \end{aligned}$$

The graph for ODBFs versus the RF output frequencies for m=2 and n=1 is shown in **Figure 9A**. If m=2 and n=1, then:

$$\begin{aligned} \text{ODBF}_{2,1}(960) &= (m+n)(\text{LO2}) - m(\text{LO3}) && \text{(from Equation 5)} \\ &= 3(960) - 2(1279.25) \\ &= 2880 - 2558.5 = 321.5 \text{ MHz} \end{aligned}$$

Since the desired RF output channel has a picture carrier frequency of 319.25 MHz (and assuming the bandwidth is 6 MHz for an NTSC channel), the ODBF is in-band for the desired RF output channel. From **Equation 6D**, since the ODBF is above the mid-band of the desired RF output channel, the HI-IF is moved upward. Assuming that  $\Delta$  will be a fixed value of 4 MHz, LO2' will be 964 MHz and LO3' will be 1283.25 MHz. Accordingly, from **Equation 5**:

$$\begin{aligned} \text{ODBF}_{2,1}(964) &= 3(964) - 2(964 + 319.25) \\ &= 2892 - 2566.5 = 325.5 \text{ MHz} \end{aligned}$$

The ODBF is now out of band.

In the second example, if the HI-IF is 960 MHz and the desired RF output channel has a picture carrier frequency of 481.25 MHz, we then have the following:

$$\text{LO2} = \text{HI-IF} = 960 \text{ MHz; and} \quad \text{(from Equation 2)}$$

$$\begin{aligned} \text{LO3} &= \text{HI-IF} + \text{RF output} && \text{(from Equation 3)} \\ &= 960 + 481.25 = 1441.25 \text{ MHz.} \end{aligned}$$

The graph for ODBFs versus the RF output frequencies for m=3 and n=1 is shown in **Figure 9B**. If m=3 and n=1, the ODBF can be calculated as:

$$\begin{aligned} \text{ODBF}_{3,1}(960) &= 4(960) - 3(1441.25) \quad (\text{from Equation 5}) \\ &= 3840 - 4323.75 \\ &= -483.75 \text{ MHz.} \end{aligned}$$

Since the selected channel is 481.25 MHz, (and assuming an NTSC channel), the ODBF is in-band and the HI-IF must be relocated. The result of **Equation 5** for this example is negative and the magnitude is greater than the mid-band of the desired RF output channel (481.25 MHz). Accordingly, from **Equation 6A**, the HI-IF is moved lower. Assuming that  $\Delta$  will be a fixed value of 4 MHz, LO2' will be 956 MHz and LO3' will be 1437.25 MHz. Recalculating the ODBF provides:

$$\begin{aligned} \text{ODBF}_{3,1}(956) &= 4(956) - 3(956 + 481.25) \quad (\text{from Equation 5}) \\ &= 3824 - 4311.75 = -487.75 \text{ MHz.} \end{aligned}$$

The ODBF is now out of band.

Due to the simple design of the present invention and since there are no shielding requirements to avoid ODBFs, the universal modulator may be incorporated onto a single integrated circuit. This was not possible with prior art signs.

Although the present invention has been described with reference to a settop terminal, it should be understood by

those of skill in the art that the invention is adaptable to other applications within the CATV environment, or even other communication applications which do not pertain to CATV systems.

5           For example, as shown in **Figure 7**, a prior art headend **700** generally includes two pieces of equipment; a baseband section **702** and an IF section **704**. These two sections **702**, **704** are typically designed to operate as "stand alone" units. Together, the two sections **702**, **704** output a single RF  
10       channel. The baseband section **702** generally comprises a video section **706** and an audio section **708**. These sections **706**, **708** receive audio and video baseband inputs and combine these inputs to an intermediate frequency for output to the IF section **704**. In the IF section **704**, the intermediate  
15       frequency is up-converted to the desired RF output channel. Since both sections **702**, **704** comprise units of equipment which are designed to work independently, this requires the duplication of many components between units **702**, **704**.

          Referring to **Figure 8**, a headend **800** made in accordance  
20       with the present invention is shown. The headend **800** includes an audio pre-processing section **802**, a video pre-processing section **804**, the universal modulator **808** of the present invention (which is coupled to two filters **810**, **812**), a transmitter **814** (if desired), and a microprocessor **806**,  
25       which controls all of the components of the headend **800**. As was previously described hereinbefore, since the universal modulator **808** can convert a baseband input signal to any desired RF output signal while avoiding ODBFs, the universal

modulator **808** may be utilized to replace most of the components in the baseband section **702** and the IF section **704**. This significantly reduces the number of components required for a headend **800**. Accordingly, the cost and complexity are also thereby reduced.

It should be understood by those of skill in the art, with reference to **Figure 8**, that the universal modulator **808** of the present invention may also be used to accept a baseband digital VSB signal and remodulate the signal to a desired RF output signal for use with broadcast HDTV television receivers. The universal modulator **808** could also be used to transmit RF signals to devices which require high frequency RF signals, including wireless appliances such as a cordless telephone or a wireless LAN receiver. In such an application, the second mixer up-converts the HI-IF signal to a higher frequency RF signal, instead of down-converting the HI-IF as previously described. The desired RF output signal would be:

$$\text{RF output} = (\text{HI-IF}) + \text{LO3} \quad (\text{Equation 10})$$

The RF output signal may then be transmitted directly to the wireless appliance.

## WE CLAIM:

1. A communication module which receives an input RF signal and converts said input RF signal to a desired RF output signal (105), the communication module comprising:

5 a first frequency agile local oscillator (49) for generating a first frequency for mixing with said input RF signal to generate a high intermediate frequency (HI-IF) signal;

a second frequency agile local oscillator (51) for generating a second frequency for mixing with said HI-IF signal to generate said desired RF output signal (105);

10 a processor including:

a controller for controlling said first and second frequency agile local oscillators (49, 51) to obtain said desired RF output signal (105); and

15 a comparator for comparing said first frequency with said second frequency to determine whether any interfering oscillator difference beat frequencies (ODBFs) exist within the bandwidth of said desired RF output signal (105), and for calculating a delta value to avoid said ODBFs; whereby said processor adjusts said first and second frequency agile local  
20 oscillators by said delta value such that said first and second frequencies move said interfering ODBFs outside the bandwidth of said desired RF output signal (105).

2. The communication module of claim 1 wherein the communication module receives a plurality of input RF signals and said communication module further includes a signal selector for

selecting one of said plurality of input RF signals for mixing with said first frequency.

3. The communication module of claim 1 further comprising a transmitter, for wirelessly transmitting said RF output signal (105) to a receiver.

4. The communication module of claim 3, whereby said transmitted signal is transmitted within the UHF or VHF frequency bands.

5. The communication module of claim 1, whereby the communication module is encompassed within a single integrated circuit.

6. The communication module of claim 1, whereby the communication module comprises an RF receiver circuit.

7. The communication module of claim 1, whereby the communication module comprises an RF transmitter circuit.

8. The communication module of claim 1 wherein said selected signal represents an analog signal transmission.

9. The communication module of claim 1 wherein said selected signal represents a digital signal transmission.

10. The communication module of claim 2 wherein said processor further comprises collateral memory for storing a channel map of channels to predetermined channel carrier frequencies; whereby said processor receives a specific channel selection request and determines said initial first local oscillator frequency.

11. A universal modulator for receiving a plurality of baseband input signals and outputting a desired RF output signal (105) comprising:

a first PLL frequency synthesizer (41) for generating a first frequency for mixing with a baseband audio signal to relocate said baseband audio signal within a desired bandwidth;

a second PLL frequency synthesizer (49) for generating a second frequency for mixing with a summed signal within the desired bandwidth which includes said relocated baseband audio signal and a baseband video signal to produce a HI-IF signal;

a third PLL frequency synthesizer (51) for generating a third frequency for mixing with said HI-IF signal to produce an RF output signal (105); and

a processor for selecting said first (41), second (49) and third (51) PLL frequency synthesizers based upon said desired RF output signal (105) whereby said processor:

determines a first PLL frequency for said first synthesizer (41);

determines a second initial PLL frequency for said second synthesizer (49);

compares said second initial PLL frequency with a third initial PLL frequency for said third synthesizer (51) to determine whether any interfering oscillator difference beat frequencies exist within the bandwidth of said RF output signal (105); and

adjusts said second and third initial PLL frequencies to move any interfering ODBFs out of the bandwidth of said RF output signal (105).

12. A method for receiving an input RF signal and converting said input RF signal to a desired RF output signal (105), the method comprising:

generating a first frequency for mixing with said input RF signal to generate a high intermediate frequency (HI-IF) signal;

generating a second frequency for mixing with said HI-IF signal to generate said desired RF output signal (105);

controlling said first and second frequency agile local oscillators to obtain said desired RF output signal (105);

comparing said first frequency with said second frequency to determine whether any interfering oscillator difference beat frequencies (ODBFs) exist within the bandwidth of said desired RF output signal (105), and for calculating a delta value to avoid said ODBFs; and

adjusting said first and second frequency agile local oscillators by said delta value such that said first and second frequencies move said interfering ODBFs outside the bandwidth of said desired RF output signal.

said interfering ODBFs outside the bandwidth of said desired RF output signal.

# **ABSTRACT**

A universal modulator that accepts baseband audio and video inputs and converts the combined signal to one of a plurality of frequencies dependening upon a desired output frequency and broadcast standard. The universal modulator is coupled between baseband video and audio outputs of a settop terminal demodulator/decoder and an input of a television receiver. Configuration of the universal modulator is performed via manual input by settop terminal controls or interrogation directly by a CATV headend. A communication bus coupled to the firmware distributes addressable instructions to selectively control addressable PLL frequency synthesizers. The modulator also obviates oscillator difference beat frequencies that may manifest themselves since programmable PLL frequency synthesizers are used.

**Examiner Name**

As a below named inventor, I hereby declare that:

My residence, post office address, and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

**UNIVERSAL MODULATOR**

the specification of which (Title of the Invention)

☒ is attached hereto  
 OR

☐ was filed on (MM/DD/YYYY) as United States Application Number or PCT International

Application Number and was amended on (MM/DD/YYYY) (if applicable).

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment specifically referred to above

I acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR 1.56.

I hereby claim foreign priority benefits under 35 U.S.C. 119(a)-(d) or 365(b) of any foreign application(s) for patent or inventor's certificate, or 365(a) of any PCT international application which designated at least one country other than the United States of America, listed below and have also identified below, by checking the box, any foreign application for patent or inventor's certificate, or of any PCT international application having a filing date before that of the application on which priority is claimed.
